A Banach algebra is an algebra over the real or complex numbers which is equipped with a complete norm such that  $|xy| \leq |x||y|$ . The study of Banach algebras is a major topic in functional analysis.

The formula for the geometric series remains valid in general unital Banach algebras. The binomial theorem also holds for two commuting elements of a Banach algebra. The set of invertible elements in any unital Banach algebra is an open set, and the inversion operation on this set is continuous, (and hence is a homeomorphism) so that it forms a topological group under multiplication.

This is the first volume of a two volume set that provides a modern account of basic Banach algebra theory including all known results on general Banach \*-algebras. This account emphasises the role of \*-algebra structure and explores the algebraic results which underlie the theory of Banach algebras and \*-algebras. This first volume is an independent, self-contained reference on Banach algebra ...

Here are the main general results about Banach spaces that go back to the time of Banach's book (Banach (1932)) and are related to the Baire category theorem. According to this theorem, a complete metric space (such as a Banach space, a Fréchet space or an F-space) cannot be equal to a union of countably many closed subsets with empty interiors.

If  $A$  is a Banach space, the internal hom  $\text{hom}(A, A)$  is a unital Banach algebra (by general abstract nonsense). Any  $C^*$ -algebra (and thus every von Neumann algebra) is in particular a Banach algebra. The normed division algebras are (possibly nonassociative) Banach division algebras over  $\mathbb{R}$ .

Nowadays Banach algebras is a wide discipline with a variety of specializations and applications. This particular paper focuses on Gelfand theory | the relation between multiplicative linear functionals on a commutative Banach algebra and its maximal ideals, as well as with the spectra of its elements.
